

When the adversary writes the signal, what should verification be indexed to?

Economics

Ben-Porath, Dekel & Lipman (2014)

Verification is scarce; optimal allocation
concentrates checking on few cases

I advance: to checks that are
costly *and* uninformative

Computer science

Conitzer & Sandholm (2002)

Mechanisms are **computed** per setting;
randomisation buys tractability

I advance: recompute against
an adversary that adapts each round

Behavioral science

Anderson et al. (2016)

Warnings **habituate**; attention depletes
with reuse, and the remedy is the interface

I advance: the warning budget is
a stock that depletes, not a price

Coaching-proof verification

A mechanism counts only if its decision is invariant to everything the reporting party says. Index friction to the counterpart's record, not to testimony.

Seeded sweep (obtained)
record check: miss rate tracks $1 - p$, max deviation 0.032

Ablation (obtained)
script rate 1: miss = 1.000 with and without
habituation — two separate failure channels

Anticipated (not obtained)
on real payment data, fewer legitimate blocks
at equal interception

Dashed teal = proposed synthesis · dashed orange = anticipated, not obtained · all quantities are simulated under stipulated parameters
